SOME RESULTS ON SUBSET SELECTION  
PROCEDURES FOR DOUBLE EXPONENTIAL POPULATIONS \*

by  
Shanti S. Gupta and Yoon-Kwai Leong  
Purdue University

1. Introduction

In this paper we study the selection problems and some other related statistical inference problems for  $k$  double exponential (Laplace) populations. Before we do this, we give some discussion of the Laplace distribution, its characteristics (vs. normal, logistic and Cauchy) and its use as a model in statistics and probability.

The double exponential distribution arises as a model in some statistical problems as explained later. This distribution is also considered in robustness studies, which suggests that it provides a model with different characteristics than some of the other commonly used models such as the normal distribution. In particular, the tails of the double exponential distribution are thicker than the tails of the normal or logistic, but not as thick as the Cauchy (see p. 43, Hajék [14]). Yet the double exponential has not been used very extensively as a model. This could be due in part to the lack of available statistical techniques for this distribution, although it is likely that the experimenter has shied away from using the double exponential because it has a sharp peak in the center. However, many applications would be primarily concerned with tail probabilities, and it would seem

\*This research was supported by the Office of Naval Research contract N00014-75-C-0455 at Purdue University. Reproduction in whole or in part is permitted for any purpose of the United States Government.

that the double exponential would be a useful model if exponential tails are required.

The double exponential has some application as a model in the area of Actuarial Science, and it has been suggested as a model for the distribution of the strength of flaws in materials by Epstein [8]. Using the weakest link principle, the strength of the material should decrease as the number of flaws or volume increases. In particular, from extreme-value theory the double exponential assumption leads to the result that the mode or most probable strength decreases in proportion to  $\log n$ , where  $n$  represents the size or number of flaws of the material. In comparison, the assumption of a normal model leads to a decrease in proportion to  $(\log n)^{1/2}$ . For most applications to material strength, only the minimum flaw strength would ordinarily be observable; however, Epstein [8] suggests that there may be many other types of problems, such as a system of components in series, which might be similar from a statistical point of view. Other possible applications of the double exponential are suggested by the fact that the difference of two independent (not necessary identical) two parameter exponential variables follows the double exponential distribution, and that the logarithm of the ratios of uniform or Pareto variables follows the double exponential distribution.

In classical theory, once having assumed the form of the parent distribution, we can derive a criterion which is appropriate to this assumption. For example, under the assumption of normality, for the comparison of two means we would derive the  $t$ -statistic. It is then customary to justify the use of such a normal theory criterion in the

practical circumstance in which normality cannot be guaranteed by arguing that the distribution of the characteristic is but little affected by non-normality of the parent distribution - that is, it is robust under non-normality. However, this argument ignores the fact that if the parent distribution really differed from the normal, the appropriate criterion would no longer be the normal-theory statistic. Box and Tiao [4] reconsidered the analysis of Darwin's paired data on the heights of self and cross-fertilized plants quoted by Fisher in "The Design of Experiments (1935)". In this development the parent distribution is not assumed to be normal, but only a member of the following class of symmetric distributions

$$p(y|\theta, \sigma, \beta) = \frac{1}{\Gamma[1+\frac{1}{2}(1+\beta)] 2^{\frac{1}{2}(1+\beta)} \sigma} \exp \left\{ -\frac{1}{2} \left| \frac{y-\theta}{\sigma} \right|^{2/(1+\beta)} \right\} \quad (1.1)$$

where  $-\infty < y < \infty$ ,  $0 < \sigma < \infty$ ,  $-\infty < \theta < \infty$ ,  $-1 < \beta \leq 1$ . This class of distributions includes the normal ( $\beta=0$ ) and the double exponential ( $\beta=1$ ), and its kurtosis parameter is  $\beta$ .

If the probability density function of the double exponential is given by

$$f(x, \theta, \sigma) = \frac{1}{2\sigma} e^{-\left| \frac{x-\theta}{\sigma} \right|}, \quad -\infty < x < \infty, \quad -\infty < \theta < \infty, \quad \sigma > 0 \quad (1.2)$$

then the mode of the distribution is  $x = \theta$  where it has a sharp peak. The expected value and standard deviation of (1.2) are  $\theta$  and  $\sqrt{2} \sigma$  respectively. Moments of the standardized double exponential order statistics can be obtained by using the closed-form expressions for the

moments of the standardized negative exponential order statistics derived by Epstein and Sobel [9]. Govindarajulu [10] has given the expressions for these moments.

Chew [6] gives the graphs of the standardized density functions of normal, logistic and double exponential distributions, from which it is clear that the tails of the double exponential distribution are thicker than that of the normal or logistic, in the sense that the curve of double exponential is above that of the others to the left and right of some points. In the case of the normal distribution this point is 2.64.

If the cumulative distribution functions  $G_1(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^x e^{-\frac{1}{2}u^2} du$  and  $G_2(x) = \begin{cases} \frac{1}{2} e^{\sqrt{2}x} & , x < 0 \\ 1 - \frac{1}{2} e^{-\sqrt{2}x} & , x \geq 0 \end{cases}$  of the standardized normal and double

exponential distributions are compared, (also similar comparison between standardized logistic  $G_3(x) = 1/(1 + e^{-\frac{\pi}{\sqrt{3}}x})$  and the double exponential distribution) the differences  $G_2(x) - G_1(x)$  (as well as  $G_2(x) - G_3(x)$ ) vary in the way shown in the graph below. Since  $G_1(x)$ ,  $G_2(x)$  and  $G_3(x)$  are symmetric about  $x = 0$  only the values for  $x \geq 0$  are shown.

With regard to point estimation, it is well known that the maximum likelihood estimates based on the complete sample of size  $n$  are given by  $\hat{\theta} = \tilde{X}$  and  $\hat{\sigma} = \frac{1}{n} \sum_{i=1}^n |X_i - \tilde{X}|$ , where  $\tilde{X}$  denotes the sample median.

Also best linear estimators (based on order statistics) under symmetric censoring are given by Govindarajulu [11] for sample sizes up to 20, and some alternate estimates are suggested by Raghunandan and Srinivasan [16]. Interval estimation for the parameters of the

two-parameter double exponential distribution is considered by Bain and Engelhardt [1].

Now we discuss the problem of comparison of  $k (\geq 2)$  double exponential distributions. First we study the selection problem for the largest mean (location).

## 2 Selecting a Subset Containing the Best of Several Double Exponential Populations with Respect to the Location Parameter

### (A) Formulation of the Problem

Let  $X_i$ ,  $i = 1, 2, \dots, k$  be  $k$  independent random variables from double exponential population  $\pi_i$ ,  $i = 1, 2, \dots, k$  respectively, with probability density function

$$f(X; \theta_i, \sigma) = \frac{1}{2\sigma} \exp [-|X - \theta_i|/\sigma], \quad -\infty < x < \infty, \quad -\infty < \theta_i < \infty, \quad \sigma > 0$$

where  $\sigma$  is a common, known constant for each of the  $k$  populations. We may, without loss of generality, assume  $\sigma$  to be one. The ranked parameters are denoted by  $\theta_{[1]} \leq \theta_{[2]} \leq \dots \leq \theta_{[k]}$ . As before, it is assumed that there is no a priori information available about the correct pairing of the ordered  $\theta_{[i]}$  and the  $k$  given populations from which observations are taken. Any population whose parameter value equals  $\theta_{[k]}$  will be defined as a best population. A correct selection (CS) is defined as the selection of any subset of the  $k$  given populations which contains at least one best population.

Suppose we take  $(2n+1)$  independent observations from  $\pi_i$ ,  $i = 1, 2, \dots, k$ ; the sample size  $(2n+1)$  is assumed to be given in the primary problem below. Let  $P^*(\frac{1}{k} < P^* < 1)$  be a preassigned constant.

Let  $P(\text{CS}; k, n, \underline{\theta}, R)$  denote the probability of a correct selection when the procedure  $R$  is used with the given  $k, n$  and when the true configuration of parameter values is  $\underline{\theta} = (\theta_1, \theta_2, \dots, \theta_k)$ ; let the space of all possible values of  $\underline{\theta}$  be denoted by  $\Omega$ .

The problem of primary interest is to define a procedure  $R$  which selects a subset of the  $k$  given populations that is small, never empty, and large enough so that it contains the best population with probability at best  $P^*$ , regardless of the true configurations  $\underline{\theta}$  in  $\Omega$ , i.e., so that

$$\inf_{\Omega} P(\text{CS}; k, n, \underline{\theta}, R) \geq P^* . \quad (2.1)$$

After having defined a particular procedure  $R = R(k, n, P^*)$  for each possible set of values of  $k, n$  and  $P^*$ , we discuss the expected size  $E\{S; k, n, \underline{\theta}, P^*, R\}$  of the selected subset when the procedure  $R$  is used with the given  $k, n, P^*$  and where  $\underline{\theta}$  is the true parameter configuration in  $\Omega$ .

Let  $Y_i$  denote the sample median of the  $(2n+1)$  observations  $X_{i1}, \dots, X_{i,2n+1}$ , from the  $i$ th population, and let  $Y_{(i)}$  denote that unknown variable which is associated with  $\theta_{[i]}$ . The probability density  $g_n(\cdot)$  and the cumulative distribution  $G_n(\cdot)$  of  $Y_i$  are given by

$$g_n(y; \theta_i) = \frac{(2n+1)!}{n!n!} \left(\frac{1}{2} e^{-|y-\theta_i|}\right)^{n+1} \left(1 - \frac{1}{2} e^{-|y-\theta_i|}\right)^n \quad (2.2)$$

$$G_n(y; \theta_i) = \begin{cases} 1 - \sum_{j=0}^n \binom{2n+1}{j} \left(\frac{1}{2} e^{y-\theta_i}\right)^j \left(1 - \frac{1}{2} e^{y-\theta_i}\right)^{2n+1-j}, & y < \theta_i \\ \sum_{j=0}^n \binom{2n+1}{j} \left(\frac{1}{2} e^{-(y-\theta_i)}\right)^j \left(1 - \frac{1}{2} e^{-(y-\theta_i)}\right)^{2n+1-j}, & y \geq \theta_i \end{cases} \quad (2.3)$$

Now, we propose the selection procedure  $R_1$  as follows:

$R_1$ : Retain in the selected subset only those populations  $\pi_i$  for which

$$Y_i \geq \max_{1 \leq j \leq k} Y_j - d \quad (2.4)$$

where  $d = d(k, n, P^*)$  is the smallest non-negative constant to be determined that will satisfy the basic probability requirement (2.1) for all configurations  $\underline{\theta} = (\theta_1, \theta_2, \dots, \theta_k)$ .

(B) Probability of a Correct Selection and Its Infimum

The following result concerning the rule  $R_1$  can be proved.

Theorem 2.1.  $\inf_{\underline{\theta} \in \Omega} P_{\underline{\theta}}(CS|R_1) = \inf_{\underline{\theta} \in \Omega_0} P_{\underline{\theta}}(CS|R_1) = \int_{-\infty}^{\infty} G_n^{k-1}(y+d) g_n(y) dy$

where  $\Omega_0 = \{\underline{\theta} = (\theta_1, \dots, \theta_k) : \theta_1 = \theta_2 = \dots = \theta_k = \theta\}$ ,  $G_n(y)$ ,  $g_n(y)$  are the cdf and pdf of the sample median of  $(2n+1)$  observations from the standard double exponential distribution.

Proof. For  $\underline{\theta} \in \Omega$ ,

$$\begin{aligned} P_{\underline{\theta}}(CS|R_1) &= P_{\underline{\theta}}\{Y_{(k)} \geq \max_{1 \leq j \leq k} Y_{(j)} - d\} \\ &= P_{\underline{\theta}}\{Y_{(k)} - \theta_{[k]} \geq Y_{(j)} - \theta_{[j]} + \theta_{[j]} - \theta_{[k]} - d, j=1, 2, \dots, k-1\} \\ &= \int_{-\infty}^{\infty} \left[ \prod_{j=1}^{k-1} \int_{-\infty}^{y+\theta_{[k]} - \theta_{[j]} + d} g_n(z) dz \right] g_n(y) dy. \quad (2.5) \end{aligned}$$

Note that  $\theta_{[k]} - \theta_{[j]} \geq 0$  for  $j = 1, \dots, k-1$ ; thus the result follows.

Hence, if we choose  $d$  to be the smallest constant to satisfy

$$\int_{-\infty}^{\infty} G_n^{k-1}(y+d) g_n(y) dy = P^*, \quad (2.6)$$

then we have determined the constant  $d$  for which

$$\inf_{\underline{\theta} \in \Omega} P_{\underline{\theta}}(CS|R_1) = P^* . \quad (2.7)$$

(c) Some Properties of  $R_1$

For  $\underline{\theta} \in \Omega$  and  $\underline{\theta} = (\theta_{[1]}, \dots, \theta_{[k]})$  define  $P_{\underline{\theta}}(i) = P_{\underline{\theta}}\{R \text{ select population } \pi_{(i)}\}$ , and recall the following definitions (see Santner [7]).

Definition 2.1. The rule  $R$  is strongly monotone in  $\pi_{(i)}$  means

$$P_{\underline{\theta}}(i) \text{ is } \begin{cases} \uparrow \text{ in } \theta_{[i]} \text{ when all other components of } \underline{\theta} \text{ are fixed} \\ \uparrow \text{ in } \theta_{[j]} \text{ (} j \neq i \text{) when all other components of } \underline{\theta} \text{ are fixed} \end{cases}$$

Definition 2.2.  $R$  is a monotone procedure means for every  $\underline{\theta} \in \Omega$  and  $1 \leq i < j \leq k$ ,  $P_{\underline{\theta}}(i) \leq P_{\underline{\theta}}(j)$ .

Definition 2.3.  $R$  is an unbiased procedure means for every  $\underline{\theta} \in \Omega$  and  $1 \leq j < k$ ,

$$P_{\underline{\theta}}\{R \text{ does not select } \pi_{(i)}\} \geq P_{\underline{\theta}}\{R \text{ does not select } \pi_{(k)}\}$$

Of course, if  $R$  is monotone it is also unbiased.

Theorem 2.2. For any  $i = 1, 2, \dots, k$ , the procedure  $R_1$  is strongly monotone in  $\pi_{(i)}$ .

Proof. The proof follows easily from the expression

$$P_{\underline{\theta}}(i) = \int_{-\infty}^{\infty} \left\{ \prod_{\substack{j=1 \\ j \neq i}}^k G_n(y + \theta_{[i]} - \theta_{[j]} + d) \right\} g_n(y) dy .$$

Corollary 2.1. The rule  $R_1$  is monotone and unbiased.

Proof. It is known and easy to see that if  $R$  is strongly monotone in

$\pi(i)$ , for all  $i = 1, 2, \dots, k$ , then it is monotone.

Now we consider some special configurations of  $\underline{\theta} \in \Omega$ .

$$\begin{cases} \theta_{[i]} = \theta, & i = 1, 2, \dots, k-1 \\ \theta_{[k]} = \theta + \Delta, & \Delta > 0 \end{cases} \quad (2.8)$$

$$\theta_{[i]} = \theta + (i-1)\Delta, \quad \Delta > 0, \quad i = 1, 2, \dots, k. \quad (2.9)$$

Under (2.8),

$$p_{\underline{\theta}}(i) = \int_{-\infty}^{\infty} [G_n(y+d)]^{k-2} G_n(y+d-\Delta) g_n(y) dy \quad \text{for } i=1, 2, \dots, k-1 \quad (2.10)$$

$$p_{\underline{\theta}}(k) = \int_{-\infty}^{\infty} [G_n(y+d+\Delta)]^{k-1} g_n(y) dy. \quad (2.11)$$

While under (2.9),

$$p_{\underline{\theta}}(i) = \int_{-\infty}^{\infty} \left\{ \prod_{\substack{j=1 \\ j \neq i}}^k G_n(y+d+(i-j)\Delta) \right\} g_n(y) dy, \quad i=1, 2, \dots, k.$$

From the above equations we can make the following remarks:

Remark 2.1. For fixed  $P^*$ ,  $k$ ,  $n$ ,  $i$  ( $i = 1, 2, \dots, k-1$ ), the probability of selecting population  $\pi(i)$  decreases from  $P^*$  to zero as  $\Delta$  increases from zero to infinity.

Remark 2.2. For fixed  $P^*$ ,  $k$  and  $n$ , the probability of selecting  $\pi(k)$  increases from  $P^*$  to one as  $\Delta$  increases from zero to infinity.

Remark 2.3. For fixed  $P^*$ ,  $k$ ,  $i$  ( $i=1, \dots, k-1$ ) and  $\Delta$ , the probability of selecting population  $\pi(i)$  tends to zero as  $n \rightarrow \infty$ . While the probability of selecting  $\pi(k)$  tends to one as  $n \rightarrow \infty$ .

Conclusion: Under either configuration (2.8), (2.9),

$E_{\underline{\theta}}(S|R_1) = \sum_{i=1}^k p_{\underline{\theta}}(i) \rightarrow 1$  as  $\Delta \rightarrow \infty$  for fixed  $n$  and  $E_{\underline{\theta}}(S|R_1) \rightarrow 1$  as  $n \rightarrow \infty$  for fixed  $\Delta$ .

(D) Asymptotic Results for the Procedure  $R_1$

It suffices to consider the parameter space  $\Omega_0$ . For  $n$  large, we discuss an asymptotic property of the procedure as follows. Let  $Y$  be the sample median from a sample of size  $(2n+1)$  with pdf  $f(x;\theta) = \frac{1}{2} e^{-|x-\theta|}$ ,  $-\infty < x < \infty$ . Then it is known (see Chu [7]) that under  $\Omega_0$ ,  $\frac{Y-\theta}{\sigma_n}$  is asymptotically normally distributed (here  $\sigma_n^2 = \frac{1}{2n+1}$ ). Let  $Z$  denote a random variable which has a standard normal distribution, then  $\frac{Y-\theta}{\sigma_n}$  is asymptotically distributed as  $Z$ . Hence, under  $\Omega_0$ , the probability

$$Y_k \geq \max_{1 \leq j \leq k} Y_j - d$$

is asymptotically, the same as the probability

$$Z_k \geq \max_{1 \leq j \leq k} Z_j - \sqrt{2n+1} d \quad (2.13)$$

where  $Z_i$ ,  $i = 1, 2, \dots, k$ , are iid standard normal variables. Hence,

$$\begin{aligned} \inf_{\underline{\theta} \in \Omega_0} P_{\underline{\theta}}(CS|R_1) &\approx P_{\underline{\theta}}\{Z_k \geq \max_{1 \leq j \leq k} Z_j - \sqrt{2n+1} d\} \\ &= \int_{-\infty}^{\infty} \left[ \Phi(z + \sqrt{2n+1} d) \right]^{k-1} d\Phi(z) \end{aligned}$$

where  $\Phi(\cdot)$  is the cdf of the standard normal distribution.

(E) The Monotone Likelihood Ratio Property of the Sample Median

Suppose  $Y$  is the sample median of  $(2n+1)$  observations from the population with double exponential density function  $f(x;\theta) = \frac{1}{2} e^{-|x-\theta|}$ .

The pdf  $g_n(y; \theta)$  and cdf  $G_n(y; \theta)$  of  $Y$  are given by equations (2.2) and (2.3).

After some algebraic computations, we see that  $G_n(\theta; \theta) = \frac{1}{2}$ ; also it is easy to show that  $g_n(y; \theta)$  is differentiable at  $y = \theta$ .

Let  $g_n(y; \theta) = \bar{g}_n(y - \theta)$ . It is shown in Lehmann [15, p.330] that a necessary and sufficient condition for  $\bar{g}_n(y - \theta)$  to have monotone likelihood ratio in  $y$  is that  $-\log \bar{g}_n$  is convex. Our main goal in this section is to prove this assertion. Now

$$\bar{g}_n(y) = c_n \left(\frac{1}{2} e^{-|y|}\right)^{n+1} \left(1 - \frac{1}{2} e^{-|y|}\right)^n \text{ where } c_n = \frac{(2n+1)!}{n!n!}, \text{ so,}$$

$$-\log \bar{g}_n(y) = -\log c_n + (n+1) \log 2 + (n+1)|y| - n \log \left(1 - \frac{1}{2} e^{-|y|}\right).$$

Let  $h(y) = (n+1)|y| - n \log \left(1 - \frac{1}{2} e^{-|y|}\right) = \begin{cases} h_1(y) & , y < 0 \\ h_2(y) & , y \geq 0 \end{cases}$  which is

a continuous function. For  $y < 0$ ,

$$h(y) = h_1(y) = -(n+1)y - n \log \left(1 - \frac{1}{2} e^y\right), \text{ we have}$$

$$h'_1(y) = -(n+1) + \frac{\frac{n}{2} e^y}{1 - \frac{1}{2} e^y} < 0 \text{ since for } y < 0, \frac{\frac{1}{2} e^y}{1 - \frac{1}{2} e^y} < 1$$

and  $h''_1(y) = \frac{\frac{n}{2} e^y}{\left(1 - \frac{1}{2} e^y\right)^2} > 0$ .

Hence, for  $y < 0$ ,  $h_1(y)$  is a decreasing, convex function. Similarly, for  $y \geq 0$ ,

$$h(y) = h_2(y) = (n+1)y - n \log \left(1 - \frac{1}{2} e^{-y}\right)$$

$$h'_2(y) = n+1 - \frac{\frac{n}{2} e^{-y}}{1 - \frac{1}{2} e^{-y}} > 0 \text{ since for } y \geq 0, \frac{\frac{1}{2} e^{-y}}{1 - \frac{1}{2} e^{-y}} < 1$$

$$h''_2(y) = \frac{\frac{n}{2} e^{-y}}{\left(1 - \frac{1}{2} e^{-y}\right)^2} > 0$$

Hence, for  $y \geq 0$ ,  $h_2(y)$  is an increasing, convex function. Note that  $h(y)$  is continuous at  $y = 0$ , decreasing, convex for  $y < 0$  and increasing, convex for  $y \geq 0$ . Hence, this concludes that  $h(y)$  is a convex function, which implies  $-\log \bar{g}_n(y)$  is also a convex function.

Theorem 2.3.  $g_n(y; \theta)$  has monotone likelihood ratio in  $y$ .

(F) Expected Size of the Selected Subset

The procedure  $R_1$  satisfies the basic probability requirement (2.1) and is defined by (2.4). Consistent with the basic probability requirement, we would like the size of the selected subset to be small. Now  $S$ , the size of the selected subset is a random variable which takes integer values  $1, 2, \dots, k$ . Hence, one criterion of the efficiency of the procedure  $R_1$  is the expected value of the size of the subset. Now, we derive an expression for  $E(S|R_1)$ , the expected size of the selected subset using procedure  $R_1$ .

$$\begin{aligned} E(S|R_1) &= \sum_{i=1}^k P\{\text{Selecting the population with parameter } \theta_{[i]}\} \\ &= \sum_{i=1}^k P\{Y_{(i)} \geq \max_{1 \leq j \leq k} Y_{(j)} - d\} \\ &= \sum_{i=1}^k \int_{-\infty}^{\infty} \left[ \prod_{\substack{j=1 \\ j \neq i}}^k G_n(y + d + \theta_{[i]} - \theta_{[j]}) \right] g_n(y) dy. \quad (2.16) \end{aligned}$$

If we set the  $m$  smallest parameters  $\theta_i$  ( $1 \leq m < k$ ) equal to a common value  $\theta$  (say) and define

$$Q = E(S \mid \theta_{[1]} = \dots = \theta_{[m]} = \theta) \quad (2.17)$$

then by an analogous argument as in Gupta [13] one can prove the following theorem.

Theorem 2.4. For given  $k$ ,  $P^*(\frac{1}{k} < P^* < 1)$ , the expected size of the selected subset  $E(S \mid \theta_{[1]} = \theta_{[2]} = \dots = \theta_{[m]} = \theta, m < k)$  in using the procedure  $R_1$  is strictly increasing in  $\theta$ .

Corollary 2.2.  $\sup_{\theta \in \Omega} E_{\theta}(S \mid R_1) = k \int_{-\infty}^{\infty} G_n^{k-1}(y+d) g_n(y) dy = k P^*.$

Corollary 2.3. In the subset  $\Omega(\delta) = \{\theta: \theta_{[i]} \leq \theta_{[k]} - \delta, i = 1, 2, \dots, k-1\}$ , the function  $E_{\theta}(S \mid R_1)$  takes on its maximum value when  $\theta_{[i]} = \theta_{[k]} - \delta, i = 1, 2, \dots, k-1$ , and so

$$\begin{aligned} \sup_{\theta \in \Omega(\delta)} E_{\theta}(S \mid R_1) &= \int_{-\infty}^{\infty} G_n^{k-1}(y+d+\delta) g_n(y) dy \\ &+ (k-1) \int_{-\infty}^{\infty} G_n^{k-2}(y+d) G_n(y+d-\delta) g_n(y) dy. \end{aligned}$$

#### (G) Minimax Property of the Rule $R_1$

Suppose that  $y_1, \dots, y_k$  are the sample medians from the  $k$  populations  $\pi_1, \dots, \pi_k$ , respectively, and with this set of observations, we select the  $i$ th population with probability  $\phi_i(y_1, \dots, y_k)$ . Then the selection rule  $R$  is said to be invariant or symmetric if

$$\phi_i(y_1, \dots, y_i, \dots, y_j, \dots, y_k) = \phi_j(y_1, \dots, y_j, \dots, y_i, \dots, y_k)$$

for all  $i$  and  $j$ , i.e. if  $y_j$  is observed from  $\pi_i$  and  $y_i$  from  $\pi_j$ , then we select the  $j$ th population with the same probability  $\phi_i(y_1, \dots, y_k)$ .

Notice that the rule  $R_1: Y_i \geq \max_{1 \leq j \leq k} Y_j - d$  satisfies the equations

$$\inf_{\theta \in \Omega} P_{\theta}(CS \mid R_1) = \inf_{\theta \in \Omega_0} P_{\theta}(CS \mid R_1) = P_{\theta_0}(CS \mid R_1) = P^* \quad (2.20)$$

$$\text{and } \sup_{\underline{\theta} \in \Omega} E_{\underline{\theta}}(S|R_1) = \sup_{\underline{\theta} \in \Omega_0} E_{\underline{\theta}}(S|R_1) = E_{\underline{\theta}_0}(S|R_1) = k P^* \quad (2.21)$$

where  $\underline{\theta}_0 = (\theta_0, \dots, \theta_0)$ .

For any invariant rule  $R'$ ,  $\underline{\theta}_0 \in \Omega$ ,

$$\begin{aligned} E_{\underline{\theta}_0}(S|R') &= \sum_{i=1}^k P_{\underline{\theta}_0} \{\text{select population } \pi_i | R'\} \\ &= \sum_{i=1}^k \int \phi_i(y_1, \dots, y_k) \left[ \prod_{j=1}^k g_n(y_j) \right] dy_1 \dots dy_k \\ &= k P_{\underline{\theta}_0}(CS|R'). \end{aligned}$$

Hence for  $\underline{\theta}_0 \in \Omega_0$ ,

$$E_{\underline{\theta}_0}(S|R') - E_{\underline{\theta}_0}(S|R_1) = k [P_{\underline{\theta}_0}(CS|R') - P_{\underline{\theta}_0}(CS|R_1)] \quad (2.22)$$

If the rule  $R'$  satisfies the basic  $P^*$  condition, it follows from (2.20) that the right hand side of (2.22) is non-negative. Thus

$$E_{\underline{\theta}_0}(S|R') \geq E_{\underline{\theta}_0}(S|R_1) = \sup_{\underline{\theta} \in \Omega} E_{\underline{\theta}}(S|R_1).$$

So that  $\sup_{\underline{\theta} \in \Omega} E_{\underline{\theta}}(S|R') \geq \sup_{\underline{\theta} \in \Omega} E_{\underline{\theta}}(S|R_1)$

i.e. the rule  $R_1$  is minimax among all invariant rules satisfying the  $P^*$ -condition.

### 3. Selecting the Population with the Largest Location Parameter - Indifference Zone Approach

In this section, we would like to use the indifference zone approach of Bechhofer [3] to select one population which is guaranteed to be associated with the largest location parameter with a fixed probability  $P^*$  whenever the unknown parameters lie outside some subset,

or zone of indifference, of the entire parameter space. The goal is to define a sequence of rules  $\{R_2(n)\}$  each of which selects a single population  $\pi_{(k)}$  and find the smallest  $n$  so that

$$P_{\underline{\theta}}(CS|R_2(n)) \geq P^*, \forall \underline{\theta} \in \Omega(\delta^*) = \{\underline{\theta}: \theta_{[k]} - \theta_{[k-1]} \geq \delta^*\} \quad (3.1)$$

where  $P^*$  and  $\delta^*$  are preassigned numbers.

For the sake of clarity, we will use the notation  $Y_{[k]n}$  to denote the largest of the sample medians each based on  $(2n+1)$  observations.

$R_2(n)$ : Select the population corresponding to  $Y_{[k]n}$ .

Let  $\Omega_0(\delta^*) = \{\underline{\theta}: \theta_{[1]} = \dots = \theta_{[k-1]} = \theta_{[k]} - \delta^*\}$ . Then we have the following theorem.

Theorem 3.1.  $\inf_{\underline{\theta} \in \Omega(\delta^*)} P_{\underline{\theta}}(CS|R_2(n)) = \inf_{\underline{\theta} \in \Omega_0(\delta^*)} P_{\underline{\theta}}(CS|R_2(n))$

Proof. For  $\underline{\theta} \in \Omega(\delta^*)$ ,

$$\begin{aligned} P_{\underline{\theta}}(CS|R_2(n)) &= P_{\underline{\theta}}\left\{\max_{1 \leq j \leq k-1} Y_{(j)n} < Y_{(k)n}\right\} \\ &= P_{\underline{\theta}}\{Y_{(j)n} < Y_{(k)n}, j = 1, 2, \dots, k-1\} \\ &= P_{\underline{\theta}}\{Y_{(j)n}^{-\theta_{[j]}} < Y_{(k)n}^{-\theta_{[k]} + \theta_{[k]} - \theta_{[j]}}, j = 1, 2, \dots, k-1\} \\ &= \int_{-\infty}^{\infty} \left[ \prod_{j=1}^{k-1} G_n(y + \delta_{kj}) \right] d G_n(y) \end{aligned} \quad (3.2)$$

where  $G_n(y) = G_n(y; 0)$  is the cdf of the sample median of  $(2n+1)$

independent observation from the standard double exponential distribution with density function  $\frac{1}{2} e^{-|x|}$ ,  $-\infty < x < \infty$ , and  $\delta_{kj} = \theta_{[k]} - \theta_{[j]} \geq 0$ .

Hence the infimum of the probability of a correct selection occurs when

$$\theta_{[1]} = \theta_{[2]} = \dots = \theta_{[k-1]} = \theta_{[k]} - \delta^* \text{ provided } \theta_{[k]} - \theta_{[k-1]} \geq \delta^*.$$

This proves the theorem.

The minimum sample size required to achieve the  $P^*$  condition  
 (3.1) is the smallest integer  $n$  such that

$$\int_{-\infty}^{\infty} [G_n(y + \delta^*)]^{k-1} dG_n(y) \geq P^*. \quad (3.3)$$

#### 4 Selecting the t-Best Populations - Indifference Zone Approach

Now, we consider the problem of selecting the best  $t$  populations, i.e., the populations with location parameters  $\theta_{[k-t+1]}, \theta_{[k-t+2]}, \dots, \theta_{[k]}$ , without regard to order. We are using the indifference zone approach based on the sample median  $Y_i$  of  $2n+1$  independent observations from population  $\pi_i$ ,  $i = 1, \dots, k$ . Define a sequence of procedures as follows:  
 $R_3(n)$ : Select the  $t$  populations associated with  $t$  largest values of  $Y_i$ .

Let  $\Omega'(\delta^*) = \{\underline{\theta}: \theta_{[k-t+1]} - \theta_{[k-t]} \geq \delta\}$  and let

$$\Omega_0'(\delta^*) = \{\underline{\theta}: \theta_{[1]} = \dots = \theta_{[k-t]} = \theta, \theta_{[k-t+1]} = \dots = \theta_{[k]} = \theta + \delta^*\}.$$

Theorem 4.1.  $\inf_{\underline{\theta} \in \Omega'(\delta^*)} P_{\underline{\theta}}\{CS|R_3(n)\} = \inf_{\underline{\theta} \in \Omega_0'(\delta^*)} P_{\underline{\theta}}\{CS|R_3(n)\}$

Proof. It was shown in Theorem 2.3 that the pdf  $g_n(y; 0)$  of the sample median has monotone likelihood ratio in  $y$ , which implies that it is stochastically increasing in  $\theta$ . Using a theorem of Barr and Rizvi [2], it follows that, for  $\underline{\theta} \in \Omega'(\delta^*)$

$$P_{\underline{\theta}}\{CS|R_3(n)\} = P_{\underline{\theta}}\left\{\max_{1 \leq i \leq k-t} Y(i) < \min_{k-t+1 \leq j \leq k} Y(j)\right\}$$

is a non-increasing function of  $\theta_{[1]}, \dots, \theta_{[k-t]}$  and a non-decreasing function of  $\theta_{[k-t+1]}, \dots, \theta_{[k]}$ . Thus  $P_{\underline{\theta}}\{CS|R_3(n)\}$  attains its infimum when  $\theta_{[1]}, \dots, \theta_{[k-t]}$  attain their maximum possible values, while

$\theta_{[k-t+1]}, \dots, \theta_{[k]}$  attain their minimum possible values subject to  $\underline{\theta} \in \Omega'(\delta^*)$ . The proof is thus completed.

Using the same notation as in Section 2, let  $G_n(y; \theta_i)$  denote the cdf of the sample median  $Y_i$  with parameter  $\theta_i$ . Since  $\theta_i$  is the location parameter,  $G_n(y; \theta_i) = G_n(y - \theta_i; 0)$  and  $G_n$  is stochastically increasing, continuous in both  $y$  and  $\theta_i$ . For  $\underline{\theta} \in \Omega'(\delta^*)$ ,

$$\begin{aligned} P_{\underline{\theta}}\{CS|R_3(n)\} &= P_{\underline{\theta}}\left\{\max_{1 \leq i \leq k-t} Y(i) < \min_{k-t+1 \leq l \leq k} Y(l)\right\} \\ &= P_{\underline{\theta}}\left\{\bigcup_{j=k-t+1}^k \{Y(j) = \min_{k-t+1 \leq l \leq k} Y(l) \text{ and } \right. \\ &\quad \left. \max_{1 \leq l \leq k-t} Y(l) < Y(j)\}\right\} \\ &= \sum_{j=k-t+1}^k \int_{-\infty}^{\infty} \prod_{\beta=1}^{k-t} G_n(y; \theta_{[\beta]}) \prod_{\substack{\alpha=k-t+1 \\ \alpha \neq j}}^k \{1 - G_n(y; \theta_{[\alpha]})\} dG_n(y; \theta_{[j]}). \end{aligned}$$

In particular, for  $\underline{\theta} \in \Omega'_0(\delta^*) \subset \Omega'(\delta^*)$ ,

$$\begin{aligned} P_{\underline{\theta}}\{CS|R(n)\} &= t \int_{-\infty}^{\infty} G_n^{k-t}(y; \theta) \{1 - G_n(y; \theta + \delta^*)\}^{t-1} dG_n(y, \theta + \delta^*) \\ &= t \int_{-\infty}^{\infty} G_n^{k-t}(y - \theta; 0) \{1 - G_n(y - \theta - \delta^*; 0)\}^{t-1} dG_n(y - \theta - \delta^*; 0) \\ &= t \int_{-\infty}^{\infty} G_n^{k-t}(y + \delta^*; 0) \{1 - G_n(y; 0)\}^{t-1} dG_n(y; 0) \end{aligned}$$

which is independent of the parameter  $\theta$ . Hence for specified values of  $\delta^*$  and  $P^*$  ( $\frac{1}{\binom{k}{t}} < P^* < 1$ ), we can solve the equation

$$t \int_{-\infty}^{\infty} G_n^{k-t}(y + \delta^*; 0) \{1 - G_n(y; 0)\}^{t-1} dG_n(y; 0) = P^*$$

for  $n$ .

### 5. Subset Selection with Respect to the Scale Parameter $\sigma$

Let  $X_i$ ,  $i = 1, 2, \dots, k$  be  $k$  independent random variables from double exponential population  $\pi_i$ ,  $i = 1, 2, \dots, k$ , respectively, with  $\pi_i$  having the probability density function

$$f(x; \theta_i, \sigma_i) = \frac{1}{2\sigma_i} \exp[-|x - \theta_i|/\sigma_i], \quad -\infty < x < \infty, \quad -\infty < \theta_i < \infty, \quad \sigma_i > 0.$$

Take  $n$  independent observations from  $\pi_i$ ,  $i = 1, 2, \dots, k$ . From these data one wishes to select a subset contains the population with the largest  $\sigma_i$ . Let  $\sigma_{[1]} \leq \dots \leq \sigma_{[k]}$  be the ordered parameters. We consider two different cases.

Case (i):  $\theta_1, \theta_2, \dots, \theta_k$  known.

In this case, the maximum likelihood estimator of  $\sigma_i$  is  $Y_i = \frac{1}{n} \sum_{j=1}^n |X_{ij} - \theta_i|$  which is distributed as a gamma variable with parameters  $n$  and  $\frac{\sigma_i}{n}$ , i.e.  $Y_i$  has density  $\frac{n}{\sigma_i \Gamma(n)} \left(\frac{ny}{\sigma_i}\right)^{n-1} e^{-\frac{ny}{\sigma_i}}$ ,  $y > 0$ . Thus the problem reduces to the one considered by Gupta [12]. The selection procedure is

R: Select the population  $\pi_i$  in the subset if and only if

$$Y_i \geq c \max_{1 \leq j \leq k} Y_j.$$

Case (ii):  $\theta_i$ 's are unknown.

When  $\theta_i$  is unknown, it is well known that the maximum likelihood estimate of  $\sigma_i$  is given by  $\hat{\sigma}_i = \frac{1}{n} \sum_{j=1}^n |X_{ij} - \tilde{X}_i|$ , where  $\tilde{X}_i$  denotes the sample median from population  $\pi_i$ . For this problem, we propose the following selection procedure.

$R_4$ : Select the population  $\pi_i$  in the subset if and only if

$$\hat{\sigma}_i \geq c_4 \max_{1 \leq j \leq k} \hat{\sigma}_j$$

where  $0 < c_4 < 1$  is so determined as to satisfy the basic probability requirement regardless of what the unknown  $\sigma_i$ 's may be.

Let  $V_i = \frac{n\hat{\sigma}_i}{\sigma_i}$ ,  $i = 1, 2, \dots, k$ . Then

$$\begin{aligned} P(CS|R_4) &= P\{\hat{\sigma}_{(k)} \geq c_4 \max_{1 \leq j \leq k-1} \hat{\sigma}_{(j)}\} \\ &= \int_0^\infty \left[ \prod_{j=1}^{k-1} F_{V_{(j)}}\left(\frac{1}{c_4} \frac{\sigma_{[k]}}{\sigma_{[j]}} x\right) \right] dF_{V_{(k)}}(x). \end{aligned}$$

So

$$\inf_{\underline{\sigma} \in \Omega'} P(CS|R_4) = \inf_{\underline{\sigma} \in \Omega'_0} P(CS|R_4) = \int_0^\infty F_V^{k-1}\left(\frac{x}{c_4}\right) dF_V(x),$$

where  $\Omega' = \{\underline{\sigma} = (\sigma_1, \dots, \sigma_k), \sigma_i > 0, i = 1, \dots, k\}$ ,

$\Omega'_0 = \{\underline{\sigma} = (\sigma, \dots, \sigma), \sigma > 0\}$  and  $F_V(\cdot)$ ,  $F_{V_{(j)}}(\cdot)$ ,  $j = 1, \dots, k$  are the cdf's of  $V = \frac{n\hat{\sigma}}{\sigma}$ ,  $V_{(j)} = \frac{n\hat{\sigma}_{(j)}}{\sigma_{[j]}}$ ,  $j = 1, \dots, k$ , respectively.

Hence if the distribution  $F_V(\cdot)$  is known, then the constant  $c_4$  can be determined by the equation

$$\int_0^\infty F_V^{k-1}\left(\frac{x}{c_4}\right) dF_V(x) = P^*.$$

The exact distribution  $F$  of  $V$  is worked out for  $n = 3$  by Bain and Engelhardt [1], and a chi-square approximation is also given by them which is quite good even for small  $n$ . However, it follows from Chernoff, Gastwirth and Johns [5], that  $\frac{1}{\sqrt{n}}(V-n) = \sqrt{n} \left[ \frac{\hat{\sigma}}{\sigma} - 1 \right]$

is asymptotically a standard normal variable. When all  $\sigma_i$  are identical

$$\begin{aligned}
P(CS|R_k) &= P\{\hat{\sigma}_k \geq c_k \hat{\sigma}_j, \quad j = 1, \dots, k-1\} \\
&= P\{\sqrt{n}(\frac{\hat{\sigma}_k}{\sigma} - 1) \geq c_k \sqrt{n}(\frac{\hat{\sigma}_j}{\sigma} - 1) + \sqrt{n}(c_k - 1), \quad j = 1, \dots, k-1\} \\
&\approx \int_{-\infty}^{\infty} \phi \left( \frac{k-1}{c_k} \frac{x - \sqrt{n}(c_k - 1)}{c_k} \right) d\phi(x).
\end{aligned}$$

#### 6. A Test of Homogeneity Based on the Sample Median Range

Let  $\pi_1, \pi_2, \dots, \pi_k$  be  $k$  independent double exponential populations such that the observations  $X_{i1}, \dots, X_{i, 2n+1}$  from  $\pi_i$  has density  $\frac{1}{2} e^{-|x - \theta_i|}$ , for  $i = 1, 2, \dots, k$ . As before, let the sample median of these  $(2n+1)$  observations be denoted as  $Y_i$ ,  $i = 1, \dots, k$ . In some practical situations one wishes to know whether  $\theta_i$  are significantly different or not. This problem is to test the homogeneity of the double exponential populations. We are interested in using a test based on the sample range of  $Y$ 's and hence we wish to derive the distribution of the sample median range  $R = \max_{1 \leq j \leq k} Y_j - \min_{1 \leq j \leq k} Y_j$ , considering all  $\theta_i$  to be equal to a common unknown  $\theta$ . When the value of  $R$  is large, the hypothesis of homogeneity is rejected. We wish to find a constant  $r$ , such that  $P(R > r) \leq \alpha$  under the hypothesis  $H_0: \theta_1 = \dots = \theta_k = \theta$ . This will provide an  $\alpha$ -level test.

Theorem 6.1. For  $\alpha$ ,  $0 < \alpha < 1$ , let  $r$  be a constant such that

$$P_{\Omega_0} \{Y_k \geq \max_{1 \leq j \leq k-1} Y_j - r\} \geq 1 - \frac{\alpha}{k}.$$

Then  $P_{\Omega_0}(R > r) \leq \alpha$ .

Proof. When  $H_0$  is true, i.e., under  $\Omega_0$ ,

$$\begin{aligned}
P(R > r) &= P\left(\max_{1 \leq j \leq k} Y_j - \min_{1 \leq j \leq k} Y_j > r\right) \\
&\leq k - \sum_{i=1}^k P\{Y_i \geq \max_{1 \leq j \leq k} Y_j - r\} \\
&= k - k P\{Y_k \geq \max_{1 \leq j \leq k-1} Y_j - r\} \\
&\leq k - k \cdot \left(1 - \frac{\alpha}{k}\right) \\
&= \alpha.
\end{aligned}$$

The above theorem establishes a connection between the selection rule  $R_1$  and the above test for equality of  $\theta$ 's.

#### 7. On the Distribution of the Statistic Associated with $R_1$

Let  $Y_i$  ( $i = 0, 1, \dots, p$ ) be  $(p+1)$  independent and identically distributed random variables each representing the median in a random sample of size  $(2n+1)$  from a population with standard double exponential density function  $f(x) = \frac{1}{2} e^{-|x|}$ . Consider the differences  $Z_i = Y_i - Y_0$  ( $i = 1, 2, \dots, p$ ). The random variables  $Z_i$  ( $i = 1, 2, \dots, p$ ) are correlated and the distribution of the maximum of  $Z_i$  is of interest in problems of selection and ranking for double exponential distribution as explained earlier when discussing  $R_1$ . In this section, we give a closed form of the distribution of  $Z = \max_{1 \leq i \leq p} Z_i$  for some special cases. We have also computed tables of the upper percentage points of  $Z = \max_{1 \leq i \leq p} Z_i$  corresponding to the probability levels  $\alpha = P^* = 0.75, 0.90, 0.95, 0.99$  for  $p = 1(1) 9$ ,  $n = 1(1) 10$ .

For the special case  $P = 1$  ( $k=2$ ),  $n = 1$  (sample size = 3), straight forward integration gives the cdf of  $Z$  (see formulae (2.2), (2.3)) as

$$\begin{aligned}
 P(Z \leq z) &= \int_{-\infty}^{\infty} G(x+z) g(x) dx \\
 &= 1 - \frac{9}{8} ze^{-2z} - \frac{3}{16} ze^{-3z} + \frac{9}{40} e^{-2z} - \frac{29}{40} e^{-3z}.
 \end{aligned}$$

Again, for  $p = 1$  ( $k=2$ ),  $n = 2$  (sample size = 5),

$$\begin{aligned}
 P(Z \leq z) &= 1 - \frac{75}{16} ze^{-3z} - \frac{225}{64} ze^{-4z} - \frac{45}{256} ze^{-5z} + \frac{10975}{1792} e^{-3z} \\
 &\quad - \frac{5225}{896} e^{-4z} - \frac{203}{256} e^{-5z}.
 \end{aligned}$$

All computations related to and given at the end of this chapter were made on a CDC 6500 using Gauss Laguerre quadrature based on fifteen nodes to perform the numerical integration. Checks on the accuracy of the program for  $p = 1$ ,  $n = 1$  showed that these values seem to be correct to three decimal places.

#### 8. An Example and Application of the Selection Rule and the Test of Homogeneity

We would like to illustrate the use of the selection procedure and the test of homogeneity of location parameters for double exponential distributions. It is known that the difference of two independent two-parameter exponential variables with the same scale parameter follows a double exponential distribution. Using a statistical package G6-RVP designed by H. Rubin and C. Hinkle at Purdue University, we generated a set of exponential random numbers, from which we obtained 5 sets of double exponential random numbers with location parameters  $\pi_i$  to be 0, 2.5, 3.4, -2.0, -0.65. Let  $\pi_i$  denote the double exponential population with location parameter  $\theta_i$  and scale parameter 1. The five pseudo-random samples from  $\pi_i$ ,  $i = 1, \dots, 5$ , are given as follows. In each case 9 observations were taken.

$\pi_1$	$\pi_2$	$\pi_3$	$\pi_4$	$\pi_5$
-3.4839	- .9839	- .0839	-5.4839	-4.1339
-2.6762	- .1762	.7238	-4.6762	-3.3262
- .3129	2.1871	3.0871	-2.3129	- .9629
- .2264	2.2736	3.1736	-2.2264	- .8764
- .1761	2.3239	3.2239	-2.1761	- .8261
.1462	2.6462	3.5462	-1.8538	- .5038
.3033	2.8033	3.7033	-1.6967	- .3467
1.6160	4.1160	5.0160	- .3840	.9660
5.6924	8.1924	9.0924	3.6924	5.0424

Let  $Y_i$  = sample median of samples of size 9. Then  $Y_1 = -.1761$ ,  $Y_2 = 2.3239$ ,  $Y_3 = 3.2239$ ,  $Y_4 = -2.1761$ ,  $Y_5 = -.8261$ . The procedure proposed for selecting a subset to include the population with largest location parameter (or median)  $\theta$  is

$R_1$ : Select population  $\pi_i$  iff  $Y_i \geq \max_{1 \leq j \leq 5} Y_j - d$ .

For  $P^* = 0.95$ , the tabulated value of the selection constant  $d$  corresponding to  $k = 5$  ( $p = 4$ ) and  $n = 4$  is 1.3210, hence  $R_1$  reduces to

$R_1$ : Select population  $\pi_i$  iff  $Y_i \geq 3.2239 - 1.3210 = 1.9029$

which selects populations  $\pi_2$  and  $\pi_3$  corresponding to the two largest values of sample medians.

For the problem of testing the hypothesis  $H: \theta_1 = \theta_2 = \dots = \theta_5$ , let  $\alpha = 0.05$ , so that  $1 - \frac{\alpha}{k} = 1 - \frac{0.05}{5} = 0.99$ ; again, we find from the table at the end of the paper that the critical value  $r$  is 1.7942. Since the sample median range

$$R = \max_{1 \leq j \leq 5} Y_j - \min_{1 \leq j \leq 5} Y_j = 3.2239 - (-2.1761) = 5.4$$

which is greater than the critical value, the hypothesis  $H: \theta_1 = \dots = \theta_5$  is rejected at 5% level of significance.

Upper  $100(1-p)^*$  percentage points of  $Z = \max_{1 \leq i \leq p} (Y_i - Y_0)$  where  $Y_0, Y_1, \dots, Y_p$  are iid sample median random variables in samples of sizes  $(2n+1)$  from the standard double exponential (Laplace) distribution.

For given  $p, n$  and  $p^* = .75$  (top),  $.90$  (second),  $.95$  (third),  $.99$  (bottom), the entries in this table are the values of  $d$  for which  $\int_{-\infty}^{\infty} G_n^p(x+d) dG_n(x) = p^*$  where  $G_n(\cdot)$  is the cdf of the median in a sample of size  $(2n+1)$  from the standard double exponential distribution.

20. ABSTRACT (Continue on reverse side if necessary and identify by block number) A subset selection procedure based on the sample medians for selecting the largest of the location parameters of k double exponential (Laplace) distributions is studied. These unknown location parameters also represent the medians or means of the double exponential populations. An indifference zone approach to the problem of selecting the populations with the t-largest unknown location parameters is discussed. For this distribution the problem of selection for the largest scale parameter is also investigated. A test of homogeneity is proposed which is based on the range of sample medians. Closed forms of the distribution

of the statistic associated with the subset selection procedure for location parameters are obtained for some special cases. Tables of the upper percentage points of this statistic are computed. An example is given to illustrate the use of the selection procedure and the test of homogeneity for the location parameters.
